Market Research

Research synthesis, the top pick, and the directions we moved away from.

Template · Content pending

The team will add its reviewed content and supporting evidence here.

Aggregate Findings

Across our market research of existing fitness alternatives, several distinct patterns emerged regarding how people approach working out independently.

We found that users value immediate feedback over post-workout analysis, as beginners and casual gym-goers frequently struggle with form but cannot consistently afford or access a personal trainer. Furthermore, research into comparable apps and tutorials showed that pre-recorded coaching videos and extensive tutorials often cause user fatigue because they feel redundant and require passive learning, leaving users wanting active guidance during their movement rather than having to pause and watch instructional clips.

Across our target audience segments, recurring patterns showed that users are willing to grant necessary camera permissions and use functional personal devices if it means minimizing injury risk, saving money on personal training, and boosting their overall gym confidence.

Ultimately, users do not need more passive instructional content. They need real-time, corrective feedback that acts as a virtual spotter to bridge the gap between working out alone and hiring an expensive personal trainer.

Top pick: Deep Dive

The single strongest finding our team landed on during our market and user research is that users demand real-time, active form correction over post-workout analysis or passive instructional videos. This insight was important because it directly addresses the primary point of our target audience: beginners and casual gym-goers who want the guidance and safety of a personal trainer but cannot consistently afford or access one. While exploring alternative tools and existing fitness apps, we discovered a major behavioral pattern where users experience high drop-off rates from pre-recorded videos because stopping to watch instructional clips interrupts their workout flow and causes cognitive fatigue.

The evidence backing this finding comes directly from our comparative analysis of existing fitness apps and user feedback segments, which revealed that users are willing to grant necessary camera permissions and use their personal devices if an application can actively monitor their movements and provide instant feedback. This minimizes injury risk and boosts gym confidence precisely when it matters most.

Abandoned Directions and Pivots

Abandoned Directions

There were a few things that didn't work out as we learned about what the market and the users wanted.

- We moved away from having passive instructional videos as most workout apps either already do this, or they simply did not add value to the users' experience when working out.
- We moved away from having trainer-led sessions in favor of a more autonomous approach, allowing users to have control over their own pace and workout

environment/style, as having personal trainers can be expensive, inaccessible due to scheduling conflicts, or intimidating due to fear of judgment.

- We moved away from having a general workout plan in favor of a more personalized approach, giving users more control over their workout routine and helping them perform exercises without injuring themselves, as people have their own limitations and abilities that may not apply to others.

Pivots

There were some pivots we made to our original idea based on the market research and user feedback.

- We will include an automatic form-detection feature, where the system will be able to detect the user's form and track it with a red outline, comparing it to the correct form displayed via a green outline. This will give users a more interactive, visual experience, helping them correct their form in real-time to prevent injury.
- On top of the automatic form-detection feature, the option to be able to record the user's workout and correction in real-time will also be available. This gives users the ability to look back at their form and progress and see how they have improved over time.
- We will include the option to select an age range and fitness level, allowing users to tailor their workout to their ability level as younger and older adults differ in strength, flexibility, and other factors.
